### ABSTRACT

The study of the orbital period variation of short-period binary systems has been important to understand several physical phenomena, such as the emission of gravitational waves, angular momentum loss via magnetic braking, matter transfer between the components, apsidal motion, quadrupole moment variation and presence of circumbinary bodies. In the latter scenario, the additional body could be a planet and is therefore crucial to understanding how these objects are formed and how they evolve around two parent stars. With the advent of large space missions, for example Kepler and TESS (Transiting Exoplanet Survey Satellite), an enormous amount of high precision photometric data with temporal coverage from years to decades has become available. Thus, in this work we propose to study the orbital period variation of a sample of 240 binary systems that was observed by the Kepler and TESS and, therefore, with a temporal coverage of more than 14 years. The main goal of this paper is the search and characterization of third bodies, however, all phenomena that generate the variation of the orbital period of binary systems will be investigated. Out of the sample of 240 binary star systems, 78 of them showed cyclic variation in their O-C diagrams and 162 of them have non-cyclic variation in the O-C diagram detected.

**Keywords:** Exoplanets (498) — Multiple stars (1081) — Eclipsing binary stars (444) — Variable star period change (1760)

### 1. INTRODUCTION

Binary stars, which consist of two stars orbiting a common center of mass, have contributed richly to several areas in Astrophysics (e.g., Sana et al. 2012; Grun-  
dahl et al. 2008; Clausen et al. 2008). A sub-  
class of these systems, the eclipsing binaries, which have  
their orbital planes in the observer’s line of sight and  
therefore eclipse each other, are used to determine dis-  
tances, and calculate fundamental parameters of stars  
(e.g. mass and radii) to test models of stellar evolution  
(e.g., Pietrzyński et al. 2012; Almeida et al. 2015, 2017).

Another topic of fundamental importance on eclipsing binary systems is the study of orbital period variation. They are used to understand various physical phenomena, e.g. emission of gravitational waves (Hulse & Taylor 1975), loss of angular momentum via mag-  
netic braking (Tout & Hall 1991), transfer of matter be-  
tween components (Tout & Hall 1991; Cehula & Pejcha  
2023), apsidal motion (Gimenez & Garcia-Pelayo 1983),

<sup>43</sup> variation of quadrupole momentum (Applegate & Pat-  
<sup>44</sup> terson 1987) and the presence of circumbinary bodies  
<sup>45</sup> (Correia et al. 2016). In the latter scenario, the addi-  
<sup>46</sup> tional bodies could be planets, and therefore, crucial to  
<sup>47</sup> understand how these objects are formed and how they  
<sup>48</sup> evolve around two parent stars (Martin & Triaud 2015).

<sup>49</sup> The characterization of binary, triple or higher order  
<sup>50</sup> systems becomes crucial for us to understand several  
<sup>51</sup> stellar physical processes, e.g. Tidal friction, Kozai cy-  
<sup>52</sup> cles, mass transfer, angular momentum loss, merging  
<sup>53</sup> (Tokovinin et al. 2006; Tokovinin 1997; Sana & Evans  
<sup>54</sup> 2010; Duchêne & Kraus 2013; Sana 2016), which we  
<sup>55</sup> would not be able to observe in isolated stars. Fur-  
<sup>56</sup> thermore, we know that the way to directly measure the  
<sup>57</sup> mass of a star is through a binary system.

<sup>58</sup> Space missions, such as Kepler and TESS (*Transit-*  
<sup>59</sup> *ting Exoplanet Survey Satellite*), have contributed signif-  
<sup>60</sup> icantly to the discoveries of planets around single stars  
<sup>61</sup> and in multiple systems (e.g., Batalha et al. 2011;

<sup>62</sup> Borucki 2016; Astudillo-Defru et al. 2020; Gандolfi et al. 2018). Kepler, launched by NASA (North American Space Agency), began its mission in 2009 and had as main scientific objective to detect exoplanets by the method of planetary transits, with emphasis on terrestrial planets ( $R < 2.5R_{\oplus}$ ), located within the habitable zones of Sun-like stars (Borucki et al. 2010). To continue with the mission to discover exoplanets, the TESS space telescope was launched in 2018 by NASA, and it is still in full operation with the aim of searching for planets that transit bright stars and close to the our Solar system (Ricker et al. 2014).

Combining data from the Kepler and TESS satellites, with temporal coverage of more than 14 years of observation, provides an excellent opportunity to study long-term phenomena. In this context, this paper aims to study the orbital period variation of the eclipsing binary systems observed by the Kepler and TESS satellites. To do so, we selected a sample of 240 eclipsing binary systems reported by Conroy et al. (2014) with data of both missions. The analysis of the orbital period variation of these systems will be done through the O-C (Observed minus Calculated) diagrams, see e.g. (Conroy et al. 2014; Almeida et al. 2019), and classified in cyclic and non-cyclic variations. For the systems with cyclic variations, it will be investigated if additional bodies can explain their O-C diagrams.

This paper is organized as follow. The Section 2 we present the data used for our study and data processing. In Section 3 we present the determination of the period of the binary system, the construction of phase diagram, the determination of the eclipse times, and the adjustment for the third body in our data. Finally, in Section 4 we present the results of this study and discuss them in Section 5.

## 2. SAMPLE SELECTION AND DATA PROCESSING

For this study, we use a sample of 240 binary systems selected out of 1279 targets reported by Conroy et al. (2014). The selection criterion was that the binaries have been observed by the Kepler and TESS satellites. Combining both data set, the temporal baseline of observations for all targets is more than 14 years. In Table 1, we list all targets with the inner binary's orbital period, eccentricity and orbital period of the third body reported by Conroy et al. (2014).

As we can see in Table 1, for some targets, e.g. KIC 3221207 and KIC 3936357, due to the relatively short temporal coverage of Kepler data, considering the long-term variations of the possible third bodies, Conroy

**Table 1.** Inner binary orbital period ( $P_{bin}$ ), orbital period ( $P_3$ ) and eccentricity ( $e_3$ ) of the third body derived by Conroy et al. (2014).

KIC	$P_{bin}$	$P_3$	$e_3$
	days	days	
2450566	1.845	$983.7 \pm 472.8$	$0.308 \pm 0.016$
3221207	0.474	$\sim 1700$	
3228863	0.731	$644.1 \pm 15.7$	$0.000 \pm 0.003$
3641446	2.100	$228.6 \pm 1.0$	$0.000 \pm 0.010$
3936357	0.369	$\sim 2400$	

NOTE—Table 1 is published in its entirety in the machine-readable format.

<sup>111</sup> et al. (2014) do not provide the values for their eccentricities.

<sup>113</sup> To search and download the Kepler and TESS light curves from the MAST webpage<sup>1</sup>, we used the <sup>114</sup> `LightCurve` python package (Lightkurve Collaboration <sup>115</sup> et al. 2018). The presearch data conditioned simple <sup>116</sup> aperture photometry (PDCSAP) flux from both Kepler <sup>117</sup> and TESS satellites have been chosen for our analysis. The PDCSAP pipeline try to remove systematic <sup>118</sup> effects, e.g. long-term trends, discontinuities within the <sup>119</sup> quarters, etc. For our sample, Kepler data are available in long cadence (30 minutes), while TESS data are <sup>120</sup> available in long (30 minutes) and short (2 minutes) <sup>121</sup> cadences. For our propose, due to best temporal precision, <sup>122</sup> we use the TESS short cadence data.

<sup>123</sup> Additional steps for the light curve preparation <sup>124</sup> were done. We use the `flatten` function from <sup>125</sup> `LightCurve` to remove the low frequency trend using the <sup>126</sup> `Savitzky-Golay` filter from Scipy package and normalize <sup>127</sup> the light curve. Besides, the `remove_outliers` function <sup>128</sup> from `LightCurve` which removes the outliers points <sup>129</sup> from the light curves based on the `sigma-clipping` algorithm <sup>130</sup> were used.

## 3. DATA ANALYSIS

<sup>134</sup> The main goal of this paper is searching for variations <sup>135</sup> in the O-C diagram of our selected binaries that could <sup>136</sup> indicate third bodies around them. To do so, we perform <sup>137</sup> the following steps: (i) determine the orbital period <sup>138</sup> of the system and build its phase diagram; (ii) perform <sup>139</sup> a Polyfit adjustment to obtain the eclipse instants and <sup>140</sup> build the O-C diagram via a linear ephemeris; and (iii)

<sup>1</sup> <https://archive.stsci.edu/>

analyze the binary orbital period variation using the O-C diagram. These steps are done in the following sections.

### 3.1. Period determination and phase diagram construction

As the Kepler and TESS data are not uniformly spaced in time, see Figure 1, to determine the binary orbital period, the Lomb-Scargle (LS) method (Lomb 1976; Scargle 1982) was used via `Lightkurve` program. Figure 2 shows the LS periodogram for the KIC 5513861 (TIC 120251815) system.

Having determined the period of the system, Fig. 2, we use the `stringlength` tool (Dworetsky 1983), a method of `pyTiming` from the PyAstronomy<sup>2</sup> library (Czesla et al. 2019), for a refinement of the obtained period. This method is suitable for non-sinusoidal periodic variations, e.g. eclipsing binaries, planetary transit, etc, returning as output the sum of the lengths among the points measured in the phase diagram, which is constructed for a period grid, see Fig. 3. The minimum output value gives the best period for the data considering the searched range.

Finally, we phase the light curve using the period of the binary system calculated in the previous step. To construct the phase diagram, we use the `fold` command of the `LightCurve` program. The result for KIC 5513861 system is shown in Figure 4.

### 3.2. Determining the period variations

To determine the eclipse times of our close binary sample, we perform the same procedure done by Conroy et al. (2014). In short, the phased light curves of the binary systems are divided in four parts and each one is fitted by a chain of nth-order polynomial  $P(x)$ , as described in Prša et al. (2008). The fitting procedure is done using a computational algorithm called `Polyfit` which is available by Prša et al. (2008). This code is based on two principles: (i)  $P(x)$  differentiable at nodes is not required, it allows to break the polynomial chain, and (ii) the nodes can change their positions iteratively driving the solution to the nearest minimum.

In our analysis, we adopt a 2nd order polynomial with 10000 iterations and step of 0.04 in phase for the search of each node. Thus, four polynomial solutions were derived and added to provide the general solution for the phased light curve, see one example in Fig 4. With respect to this last solution, we calculate the phase shift in each cycle of the binary, which multiplied by the orbital period gives the O-C diagram, see Fig. 7. A detailed

and complete description of the algorithm is available at Prša et al. (2008).

### 3.3. Search for periodic signal in the O-C Diagram

With the O-C diagram of our sample in hand, the next step is to search for periodic variations that may indicate possible additional components gravitationally interacting with the binary. To do this, we apply the same procedure as done in Section 3.1. To consider a reliable period, we adopted frequencies in the Lomb-Scargle periodogram above 10% of false alarm probability. As an example, Figure 5 shows the Lomb-Scargle periodogram generated from the O-C diagram data of KIC 5513861. In total, 78 of the 240 binaries analyzed show significant variations in their orbital period. These systems will be analyzed in the context of light travel time in the next section.

## 4. RESULTS

By analyzing the light curves of our sample of 240 close binary stars, we obtained a total of 78 systems that showed periodic variation in their O-C diagrams. For these binaries, we analyse the period variation in the context of a third component gravitationally interacting with the inner binary, see Section 4.1.

The remaining 162 objects, we do not identify any significant periodic variations, see one example in Figure 6. All results for these systems are reported in Appendix B. The analysis and discussion of the possible causes for these binaries are beyond the scope of this paper and, therefore, will be carried out in future work.

### 4.1. Light Travel Time Effect

The Light Travel Time (LTT) effect is caused by the presence of an invisible body gravitationally interacting with an object of interest, in our case a close binary system, and consists of periodic variations in the arriving time of a periodic intrinsic signal, e.g. eclipsing times, from the binary.

The variation caused by the LTT effect in the binary orbital period, can be mathematically described as follows (Irwin 1952):

$$\tau = \frac{a \sin i}{c} \frac{1 - e^2}{1 + e \cos f} \sin(f + \omega), \quad (1)$$

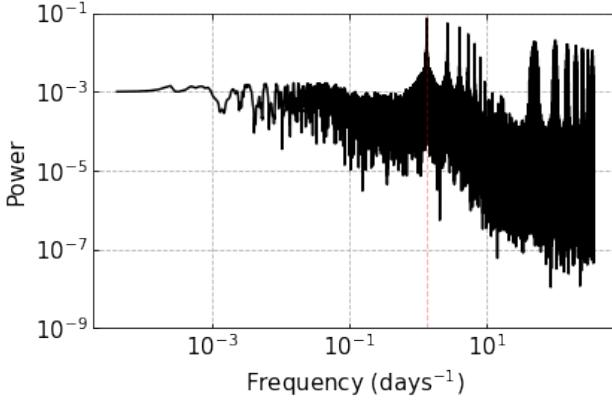

where  $a$  is the semi-major axis,  $e$  is the eccentricity,  $i$  is the orbital inclination with respect to the plane of the sky,  $\omega$  is the periastron argument,  $f$  is the true anomaly, and  $c$  the speed of light.

In addition to the LTT effect, the O-C diagram of some of these systems showed long-term changes in their orbital period. Thus, for such systems, we added a linear

<sup>237</sup> term to Eq. 1 to fit the data and obtain the general  
<sup>238</sup> solution, as illustrated in Fig. 8.

<sup>239</sup> The fitting procedure were done in two steps. Initially,  
<sup>240</sup> to find a preliminary solution, the Optimize Curve Fit

<sup>241</sup> task from SciPy library were executed. In the second  
<sup>242</sup> step, we run a Markov Chain Monte Carlo (MCMC) pro-  
<sup>243</sup>cedure through emcee program (Foreman-Mackey et al.  
<sup>244</sup> 2013), using the preliminary solution as a initial guess,

**Figure 6.** O-C diagram for the binary system KIC 1868650 (TIC 137306463).

to obtain the final solution, as well as, the error bars in each fitted parameter. Figures 7 and 8 show two results of our fitting procedure, the first with only the LTT curve and the second with the addition of the linear term. All results for the 78 systems with periodic variations are presented in Section A and the fitted parameters are listed in Table 2.

**Figure 7.** O-C diagram for the binary system KIC 5513861 (TIC 120251815). Individual and average of 20 measurements are shown with gray and black points, respectively. The red curve represents the best fit considering a third body around the inner binary.

## 5. DISCUSSIONS

Our sample of 240 close binaries were divided into two main groups: (1) systems with periodic variations in their O-C diagrams, which were fitted with an LTT curve or an LTT curve plus a linear function, and (2) systems with non-cyclic variation, which are defined as those that despite having short, increasing, decreasing or random variations in their O-C diagrams, such vari-

**Figure 8.** O-C diagram for the binary system KIC 3221207 (TIC 121213501). Individual and average of 20 measurements are shown with gray and black points. The red curve is the best solution obtained when used the sum of the LTT effect (dotted blue curve) plus the linear term (dashed green line).

ations do not have an associated period with statistical significance according to with the FAP.

Following the same criteria adopted by Conroy et al. (2014), we divided our sample with periodic variations into 3 subgroups according to the periods found in the O-C diagrams and the temporal baseline of the Kepler and TESS data: objects with (i) periods less than 2400 days ( $P < 2400$  days), (ii) periods greater or equal than 2400 and less or equal than 4800 days ( $2400 \leq P(\text{days}) \leq 4800$ ), and (iii) periods greater than 4800 days ( $P > 4800$  days). We obtained 47, 16 and 15 systems for these three subgroups, respectively. Table 2 shows these systems according to this classification and the orbital periods and eccentricities for the third body candidates.

**Table 2.** Binary systems with periodic variations in their O-C diagrams. The targets are divided in three intervals: periods less than 2400 days, between 2400 and 4800 days, and greater than 4800 days.

Table 3 present a comparison between our results with those from Conroy et al. (2014). In this table, we divided the systems with the same range of period variations as adopted by the last authors, i.e.,  $P < 700$  days, ( $700 \leq P(\text{days}) < 1400$ ), and  $P > 1400$  days. In these three ranges, we and Conroy et al. (2014) found: (i) 11 and 9 systems; (ii) 10 and 9 systems, and (iii) 57 and 16 systems, respectively. This results is illustrated in

Figure 9. Thus, as expected by adding TESS data and increasing the observational baseline, we found 78 close binaries with third body candidates, 2.3 times more systems than Conroy et al. (2014) in the sample of 240 systems. This result represents a rate of  $\sim 33\%$  in our sample of close binaries. It is also important to note that most of the new systems found are in the range of  $P > 1400$  days.

When considering the number of cycles for the third body candidates observed in the data, Conroy et al. (2014) found 9 systems with at least two cycles, 9 with

at least one cycle and 16 targets with less than one cycle, while in this study we found 47, 16 and 15 systems for same ranges, respectively.

In addition to new systems with periodic variations in their orbital periods, with the combined data from Kepler and TESS and using the MCMC procedure, we were able to better estimate the parameters of the third body candidates, such as, for example, orbital periods and eccentricities. Table 3 summarizes these parameters obtained in our fit in comparison with those from Conroy et al. (2014).

**Table 3.** Comparison between results of period and eccentricity for the third body candidates found in this paper ( $P_3$  and  $e_3$ ) and in Conroy et al. (2014) ( $P_{3,C}$  and  $e_{3,C}$ ).

305 Among the systems presented in Tables 2 and 3, there  
 306 are 60 systems that do not have values defined in the  
 307 Conroy et al. (2014) article for a possible third body,  
 308 and 16 of them have only an estimated value for the  
 309 period of the third body.

310 The relationship between the periods of the inner-  
 311 binary and the third body candidates measured in this  
 312 paper and by Conroy et al. (2014) can be visualized in  
 313 Fig. 9. There is no significant difference between our  
 314 measurements and those carried out by Conroy et al.  
 315 (2014) for the orbital period measurements of binaries.

316 It is evident that  $\sim 97\%$  of binaries with potential third  
 317 bodies have periods shorter than 4 days and that there  
 318 is no presence of binary systems with periods longer  
 319 than 12 days ( $P > 12$ ) with potential tertiary compa-  
 320 nions, consistent with results obtained by Tokovinin et al.  
 321 (2006).

322 The website [https://projectc-production.up.railway.  
 323 app/](https://projectc-production.up.railway.app/) provides the results for all close binaries, with and  
 324 without periodic orbital variations, studied in the paper.

329

## APPENDIX

330

331 Here, binary systems are listed by type of variation in their respective O-C diagrams. In Section B, those systems  
 332 with non-periodic variations are presented; in Section A those with periodic variations. And, in Section C we present  
 333 the full table with the orbital parameters found for those systems whose variations are periodic and non-periodic for  
 334 our sample of 240 eclipsing binary systems.

## 335 A. BINARY SYSTEMS WITH PERIODIC VARIATIONS ON THE O-C DIAGRAM

336 Of the 240 binary systems in our sample, a total of 13 systems, 5.42% of the sample, have periodic variations shown  
 337 in their O-C diagrams. In the following subsections we present each system with its respective characteristics for the  
 338 possible third bodies orbiting its respective binary system. For each object we derive, by adjusting for a third body,  
 339 its orbital period  $P$ , its eccentricity  $e$ , semi-major axis  $a$  and periastron argument  $\omega$ .

## 340 A.1. KIC 2450566 (TIC 137977804) Object

341 This object presents a periodic variation in its O-C diagram, Fig. 10, intuiting the presence of a third body around  
 342 the binary system with a period  $P = 1059.282^{+23.443}_{-28.695}$ , in an orbit with eccentricity  $e = 0.655^{+0.105}_{-0.066}$ , at a distance  
 343  $a = 1487.083^{+181.846}_{-150.956}$  from its parent stars, with its inclination axis  $\omega = 307.417^{+10.050}_{-17.567}$ .

**Figure 9.** Period of the inner binary versus period of the third body candidates. The blue and magenta points represent our measurement and the results from Conroy et al. (2014), respectively. The top and left histograms represent the count of binaries and third body candidates in function of the their orbital periods, respectively.

**Figure 10.** Analysis of objects KIC 2450566 (TIC 137977804). First row, left panel: Light curve from Kepler in terms of Normalized Flux over Time (BJD). Right panel: Light curve from TESS in terms of Normalized Flux over Time (BJD). Second row, left panel: Periodogram analysis to obtain the system's period. Right panel: String length to refine the obtained period. Third row, left panel: Light curve in phase - black points represent the data, and the red curve represents the best fit. Right panel: O-C diagram. Fourth row, left panel: O-C diagram with its curve adjusted for the presence of a third body; the gray points are the raw data points, the black points are the binned points, and the red curve represents the best fit for the third body around the eclipsing binary system.

344

### A.2. KIC 2708156 (TIC 122375269) Object

This object presents a periodic variation in its O-C diagram, Fig. 11, intuiting the presence of a third body around the binary system with a period  $P = 1460.490^{+2.093}_{-0.955}$ , in an orbit with eccentricity  $e = 0.396^{+0.001}_{-0.001}$ , at a distance  $a = 3690.709^{+2.778}_{-3.835}$  from its parent stars, with its inclination axis  $\omega = 191.298^{+0.425}_{-0.554}$ .

**Figure 11.** O-C diagram for the binary system KIC 2708156 (TIC 122375269).

348

### A.3. KIC 3221207 (TIC 121213501) Object

This object presents a periodic variation in its O-C diagram, Fig. 12, intuiting the presence of a third body around the binary system with a period  $P = 2253.652^{+72.383}_{-62.009}$ , in an orbit with eccentricity  $e = 0.426^{+0.048}_{-0.040}$ , at a distance  $a = 413.398^{+17.810}_{-25.905}$  from its parent stars, with its inclination axis  $\omega = 68.923^{+25.187}_{-29.382}$ .

**Figure 12.** O-C diagram for the binary system KIC 3221207 (TIC 121213501).

352      A.4. *KIC 3228863 (TIC 394179296) Object*

353      This object presents a periodic variation in its O-C diagram, Fig. 13, intuiting the presence of a third body around  
 354      the binary system with a period  $P = 663.632^{+6.202}_{-15.304}$ , in an orbit with eccentricity  $e = 0.224^{+0.173}_{-0.154}$ , at a distance  
 355       $a = 659.632^{+27.744}_{-56.636}$  from its parent stars, with its inclination axis  $\omega = 260.622^{+23.252}_{-4.142}$ .

356      **Figure 13.** Same analyses of Fig. 10, but for KIC 3228863 (TIC 394179296).

357      A.5. *KIC 3448245 (TIC 137687487) Object*

358      This object presents a periodic variation in its O-C diagram, Fig. 14, intuiting the presence of a third body around  
 359      the binary system with a period  $P = 8314.481^{+297.994}_{-89.964}$ , in an orbit with eccentricity  $e = 0.753^{+0.051}_{-0.014}$ , at a distance  
 360       $a = 298.060^{+7.057}_{-5.386}$  from its parent stars, with its inclination axis  $\omega = 0.860^{+2.637}_{-0.683}$ .

361      **Figure 14.** O-C diagram for the binary system KIC 3448245 (TIC 137687487).

360

#### A.6. *KIC 3641446 (TIC 122303843) Object*

This object presents a periodic variation in its O-C diagram, Fig. 15, intuiting the presence of a third body around the binary system with a period  $P =$ , in an orbit with eccentricity  $e =$ , at a distance  $a =$  from its parent stars, with its inclination axis  $\omega =$ .

**Figure 15.** O-C diagram for the binary system KIC 3641446 (TIC 122303843).

364

#### A.7. *KIC 3936357 (TIC 120499528) Object*

This object presents a periodic variation in its O-C diagram, Fig. 16, intuiting the presence of a third body around the binary system with a period  $P = 2132.636^{+67.619}_{-47.151}$ , in an orbit with eccentricity  $e = 0.120^{+0.075}_{-0.061}$ , at a distance  $a = 469.656^{+18.435}_{-24.562}$  from its parent stars, with its inclination axis  $\omega = 203.482^{+26.213}_{-50.987}$ .

**Figure 16.** O-C diagram for the binary system KIC 3936357 (TIC 120499528).

368      A.8. *KIC 3953981 (TIC 137152301) Object*

369      This object presents a periodic variation in its O-C diagram, Fig. 17, intuiting the presence of a third body around  
 370 the binary system with a period  $P = 2862.477^{+94.503}_{-122.901}$ , in an orbit with eccentricity  $e = 0.223^{+0.095}_{-0.069}$ , at a distance  
 371  $a = 220.574^{+19.656}_{-13.916}$  from its parent stars, with its inclination axis  $\omega = 254.738^{+28.379}_{-42.287}$ .

Figure 17. O-C diagram for the binary system KIC 3953981 (TIC 137152301).

372      A.9. *KIC 4450976, (TIC 121215583) Object*

373      This object presents a periodic variation in its O-C diagram, Fig. 18, intuiting the presence of a third body around  
 374 the binary system with a period  $P = 2546.115^{+161.201}_{-203.502}$ , in an orbit with eccentricity  $e = 0.313^{+0.150}_{-0.201}$ , at a distance  
 375  $a = 34367.104^{+2451.117}_{-2702.057}$  from its parent stars, with its inclination axis  $\omega = 297.249^{+34.620}_{-33.954}$ .

Figure 18. O-C diagram for the binary system KIC 4450976 (TIC 121215583).

376

A.10. *KIC 4451148 (TIC 121274442) Object*

This object presents a periodic variation in its O-C diagram, Fig. 19, intuiting the presence of a third body around the binary system with a period  $P = 769.411^{+6.770}_{-10.758}$ , in an orbit with eccentricity  $e = 0.466^{+0.087}_{-0.023}$ , at a distance  $a = 909.084^{+315.158}_{-185.851}$  from its parent stars, with its inclination axis  $\omega = 165.080^{+1.177}_{-7.611}$ .

**Figure 19.** Same analyses of Fig. 10, but for KIC 4451148 (TIC 121274442).

380

A.11. *KIC 4647652 (TIC 122070918) Object*

This object presents a periodic variation in its O-C diagram, Fig. 20, intuiting the presence of a third body around the binary system with a period  $P = 755.235^{+19.495}_{-13.418}$ , in an orbit with eccentricity  $e = 0.245^{+0.290}_{-0.147}$ , at a distance  $a = 636.222^{+147.225}_{-143.015}$  from its parent stars, with its inclination axis  $\omega = 239.394^{+58.689}_{-21.004}$ .

**Figure 20.** Same analyses of Fig. 10, but for KIC 4647652 (TIC 122070918).

384      A.12. *KIC 4758368 (TIC 138893145) Object*

385      This object presents a periodic variation in its O-C diagram, Fig. 21, intuiting the presence of a third body around  
 386      the binary system with a period  $P = 2473.632^{+318.289}_{-147.137}$ , in an orbit with eccentricity  $e = 0.876^{+0.083}_{-0.056}$ , at a distance  
 387       $a = 826.152^{+98.935}_{-99.057}$  from its parent stars, with its inclination axis  $\omega = 101.987^{+13.423}_{-12.392}$ .

Figure 21. Same analyses of Fig. 21, but for KIC 4758368 (TIC 138893145).

388      A.13. *KIC 4851217 (TIC 184246521) Object*

389      This object presents a periodic variation in its O-C diagram, Fig. 22, intuiting the presence of a third body around  
 390      the binary system with a period  $P = 2473.632^{+318.289}_{-147.137}$ , in an orbit with eccentricity  $e = 0.876^{+0.083}_{-0.056}$ , at a distance  
 391       $a = 826.152^{+98.935}_{-99.057}$  from its parent stars, with its inclination axis  $\omega = 101.987^{+13.423}_{-12.392}$ .

Figure 22. O-C diagram for the binary system KIC 4851217 (TIC 184246521).

392

#### A.14. *KIC 4909422 (TIC 121108244) Object*

This object presents a periodic variation in its O-C diagram, Fig. 23, intuiting the presence of a third body around the binary system with a period  $P = 6582.935^{+927.321}_{-1415.082}$ , in an orbit with eccentricity  $e = 0.839^{+0.131}_{-0.096}$ , at a distance  $a = 787.887^{+39.067}_{-99.774}$  from its parent stars, with its inclination axis  $\omega = 6.695^{+6.849}_{-4.825}$ .

**Figure 23.** O-C diagram for the binary system KIC 4909422 (TIC 121108244).

396

#### A.15. *KIC 4909707 (TIC 121119758) Object*

This object presents a periodic variation in its O-C diagram, Fig. 24, intuiting the presence of a third body around the binary system with a period  $P = 513.727^{+0.617}_{-0.517}$ , in an orbit with eccentricity  $e = 0.657^{+0.029}_{-0.027}$ , at a distance  $a = 2066.938^{+71.794}_{-65.971}$  from its parent stars, with its inclination axis  $\omega = 358.498^{+1.114}_{-1.642}$  and linear parameters fits at  $A = -6.858^{+0.110}_{-0.107}$  and  $B = 0.003^{+0.000}_{-0.000}$ .

**Figure 24.** Same analyses of Fig. 10, but for KIC 4909707 (TIC 121119758).

401 A.16. *KIC 4945588 (TIC 169079394) Object*

402 This object presents a periodic variation in its O-C diagram, Fig. 25, intuiting the presence of a third body around  
 403 the binary system with a period  $P = 1607.893^{+29.331}_{-140.789}$ , in an orbit with eccentricity  $e = 0.871^{+0.046}_{-0.045}$ , at a distance  
 404  $a = 1289.577^{+32.368}_{-66.834}$  from its parent stars, with its inclination axis  $\omega = 134.791^{+5.397}_{-6.424}$ .

Figure 25. O-C diagram for the binary system KIC 4945588 (TIC 169079394).

### A.78. KIC 12305537 (TIC 406951407) Object

653 This object presents a periodic variation in its O-C diagram, Fig. 87, intuiting the presence of a third body around  
 654 the binary system with a period  $P = 2039.912^{+9.942}_{-11.011}$ , in an orbit with eccentricity  $e = 0.736^{+0.086}_{-0.038}$ , at a distance  
 655  $a = 2946.364^{+654.431}_{-207.403}$  from its parent stars, with its inclination axis  $\omega = 5.025^{+1.976}_{-2.009}$ .

**Figure 87.** O-C diagram for the binary system KIC 12305537 (TIC 406951407).

656

## B. BINARY SYSTEMS WITH NON-PERIODIC VARIATIONS ON THE O-C DIAGRAM

657 Through the analysis of the O-C diagram of the binary systems in our sample, we were able to verify and determine  
 658 variations in certain objects, characterizing periodic variations or not in their orbital periods. Any deviations, whether  
 659 linear or periodic, in the O-C diagram could indicate changes in the orbital period over time, which could be caused  
 660 by a variety of factors, such as gravitational interactions with other stars or the presence of a third body around the  
 661 system.

662 Thus, we could observe that a percentage of, approximately, 67.5%, that is, 162 systems do not present non-  
 663 periodic variations in their O-C diagrams. This means that short-term variations in these systems do not represent  
 664 statistically significant deviations from the assumed orbital period, as determined by the False Alarm Probability  
 665 (FAP) (VanderPlas 2018). The FAP is a measure of the probability that a given deviation in the O-C diagram is due  
 666 to chance and not to an actual physical effect.

667 The absence of significant variations in the O-C diagrams of these 162 systems suggests that their orbital periods  
 668 are relatively stable over time. However, it is important to note that this does not necessarily mean that these systems  
 669 are completely stable and will not show any long-term changes in their periods. Further observations and analyzes  
 670 may be necessary to confirm the stability of these systems over longer timescales.

671 Next, in the Figs. 88-89, all these systems can be visualized with their respective light curves, periodogram,  
 672 stringlength, phase light curve and their derived O-C diagram.

673
